

Auto Ticket Classification using Flow Designer

Project Documentation

Date: 30 September 2026

1. Introduction

- **Project Title:** Auto Ticket Classification using Flow Designer
- **Team Members:**
 - **Jawahar V:** Team Lead – Flow Designer automation (Milestone 3)
 - **Ajay S:** Team Member – custom table creation (Milestone 2)
 - **Mukesh M:** Team Member – requirement analysis, field configuration, category / subcategory dependency, testing and deployment (Milestones 1, 2, 4 and 5)
 - **Mentor:** No mentor assigned yet

2. Project Overview

- **Purpose:** The school IT helpdesk receives many support requests every day from students and teachers (network connectivity, hardware failures, account access problems and system performance issues). IT staff manually review each ticket to identify the issue type, select the category and subcategory and inform the caller. The goal of this project is to automate this classification with Flow Designer so that it is faster, consistent and scalable.
- **Features:**
 - Caller enters only the Caller Name and Short Description of the issue.
 - Flow Designer is triggered on ticket submission and checks the Short Description for predefined keywords.
 - WiFi → Network / WiFi; Projector → Hardware / Projector; Password or Login → Access / Forgot Password; Slow or Hanging → Performance / Slow Computer.
 - Dependent Category and Subcategory choice fields, and email notification to the caller.
 - Basic security and access control so only authorized users can access or modify ticket data.

3. Architecture

- **User Interface (Frontend):** ServiceNow platform form and list views. The caller fills in the Caller Name and Short Description; IT staff use the list view to see classified tickets.
- **Application Logic (Backend):** A no-code Flow Designer flow with the trigger "ticket created", If / Else If conditions on the Short Description keywords, an Update Record action for Category and Subcategory, and an email notification action.
- **Database:** A custom table that stores the ticket records with the fields Caller Name, Short Description, Category and Subcategory. Subcategory choices depend on the selected Category.

4. Setup Instructions

- **Prerequisites:** A ServiceNow instance with administrator access, access to Flow Designer, and email notifications enabled on the instance.
- **Installation:** Step-by-step guide:
 1. Log in to the ServiceNow instance as an administrator.
 2. Create a new Update Set and make it the current update set.
 3. Create the custom table to store ticket records.
 4. Create the fields and configure their data types.

5. Configure the dependency between the Category and Subcategory choice fields.
6. Create the flow in Flow Designer and publish (activate) it.
7. Verify the solution using the test scenarios and mark the Update Set as Complete.

5. Application Structure

- **Tables and Fields:** Custom ticket table with Caller Name, Short Description, Category and Subcategory (choice fields with dependency).
- **Flows:** Auto Classification flow in Flow Designer (trigger, keyword conditions, update record and email notification).
- **Update Set:** Contains all the configuration changes and is used to move the solution to the target environment.

6. Running the Application

- Open the ticket form of the custom table.
- Enter the Caller Name and a Short Description such as "WiFi not working" and submit the ticket.
- Flow Designer is triggered automatically and assigns the Category and Subcategory (Network / WiFi in this example).
- Open the ticket list view to check the classification; the caller receives the email notification.

7. API Documentation

- The solution is built with no-code Flow Designer, so no custom APIs or server-side scripts were written.
- The ticket records can still be accessed through the standard ServiceNow Table API (GET / POST on /api/now/table/<table_name>) by authorized users.

8. Authentication

- Users log in to the ServiceNow instance with their credentials.
- Roles and access control rules (ACLs) make sure that only authorized users can access or modify the ticket data.

9. User Interface

- Ticket form with Caller Name and Short Description (Category and Subcategory are filled in automatically).
- List view showing the classified tickets.
- Flow Designer canvas showing the trigger and keyword conditions.

10. Testing

- **Strategy:** Validate the end-to-end automation, confirm data accuracy and confirm that only authorized users can access or modify ticket data.
- **Test Scenario 1:** Short Description contains WiFi → Category = Network, Subcategory = WiFi.
- **Test Scenario 2:** Short Description contains Projector → Category = Hardware, Subcategory = Projector.
- **Test Scenario 3:** Short Description contains Password / Login or Slow / Hanging → Access / Forgot Password or Performance / Slow Computer.
- **Tools:** ServiceNow ticket form, list view and Flow Designer execution details.

11. Screenshots or Demo

- **Demo link:** [Add demo link here]
- **Repository:** [Add repository link here]
- **Screenshots:** [Insert screenshots of the ticket form, flow and classified tickets here]

12. Known Issues

- Only the predefined keywords (WiFi, Projector, Password, Login, Slow, Hanging) are recognised; a Short Description without these keywords is not classified automatically and needs manual review.

13. Future Enhancements

- Add more keywords, categories and subcategories (for example printer, software installation, email problems).
- Automatic assignment of tickets to the right IT support group, and priority based on the issue type.
- Use AI-based classification (for example Predictive Intelligence) for descriptions that do not contain a fixed keyword.
